

Antigravity prompt: extract real product photos from the PDF

Use the supplied catalog PDF only as a source of product photographs. A crop from a PDF product-photo panel is allowed; a screenshot of the website or application is not allowed.

Do not take, generate, inspect, or use screenshots of the website or application. Do not use screenshot-based validation. Do not use terminal commands, PowerShell, shell commands, scripts, command-line tools, or terminal-generated changes. Work through the project files and editor interface only.

Do not generate new product appearances with Nano Banana. Do not redraw, redesign, replace, or hallucinate equipment. Preserve the real product's shape, controls, materials, labels, proportions, perspective, and visible branding. Use AI enhancement only after a crop is confidently matched to a specific catalog SKU, and only to improve clarity while preserving the original product exactly.

Required workflow

First, use the catalog PDF and the existing `catalog_products_normalized.js` data together. For each product record, locate the catalog page and the product-photo panel that corresponds to its model number or clearly identifiable product variant. Do not match images using category alone.

For every confident match, crop only the product-photo region from the PDF page. Exclude unrelated neighboring products, unrelated model labels, page borders, catalog navigation, and large blocks of specifications unless the photo itself requires the label for identification. Preserve the complete equipment item and do not crop away important components.

Save each crop in the project's new image folder using a safe SKU-based filename, for example:

Plain Text

```
images/catalog-products/ZQ-001-01.webp
```

Normalize image files to WebP or JPG, preserve the original aspect ratio, and use a consistent maximum web resolution. Do not enlarge a tiny crop aggressively. If enhancement is used, apply it only to the matched crop and do not alter the product's identity or technical appearance.

Add or update these fields for every product:

Plain Text

```
image: "images/catalog-products/<sku>.webp"  
imageStatus: "pdf-crop-review"  
imageSource: "catalog PDF, page <sourcePage>"  
imageVerified: true or false
```

Set `imageVerified: true` only when the SKU/model number and photo match are clear. If the match is uncertain, do not create or assign the crop. Keep the existing neutral category placeholder and set:

Plain Text

```
imageStatus: "placeholder-category"  
imageVerified: false
```

Do not silently assign one image to multiple unrelated models. If several variants share one photograph and the catalog does not clearly distinguish them, use the placeholder for those variants until a human verifies the mapping.

Mandatory image audit

Create a source-file audit record containing the product SKU, source PDF page, crop filename, match status, confidence, and reason for rejection where applicable. The audit must report exact counts for:

- Total products in the active dataset.
- Confident PDF-photo matches.
- Crops requiring human review.
- Products still using category placeholders.
- Products with no usable image.
- Duplicate image assignments.
- Missing or unreadable SKUs.

Do not claim that all products have accurate images unless every assigned crop has a clear SKU-to-photo match. Do not use screenshots for validation. Validate only by reading the project files, image filenames, metadata, and the audit data.

The final website must continue to lazy-load images, preserve the existing card aspect ratio, provide a fallback placeholder if an image fails, and use the real product name and SKU for alt text. The catalog must remain functional even when many products still use placeholders.
